## Applied Machine Learning - Recalls

Fabien BERNIER & Yann HOFFMANN, September 2023

## **Fabien BERNIER**

2<sup>nd</sup> year PhD candidate @Serval, SnT

Working on Machine Learning applied on smart grids,  
with a focus on time series forecasting.

## **Yann HOFFMANN**

1<sup>st</sup> year PhD candidate @Serval, SnT

Working on Machine Learning for financial data

## 1. Machine Learning Basics

1. Recalls
2. Interactive quiz

## 2. ML project life cycle

1. Problem and goal definition
2. Data collection and preparation
3. Feature engineering
4. Model building
5. Model evaluation

# Machine Learning basics

Recalls\*

**AI:** “any device that perceives its environment and takes actions that maximize its chance of successfully achieving its goals” [\(source\)](#)

## Machine Learning

Performing a specific task without being explicitly programmed for and using data instead.

*“How can computers learn to solve problems without being explicitly programmed?”*  
~ Arthur Samuel (1959)

Artificial Intelligence

Machine Learning

## Artificial Intelligence

### Machine Learning

Classical ML

Representation  
Learning

Deep Learning

## Classical Machine Learning

The engineer defines features from raw data. The model learns from this fixed representation

## Representation Learning

Learn both the features from raw data and how use them to perform a specific task. Replaces manual feature engineering

## Deep Learning

Representation Learning with Neural Networks

- **Example:** a person or an object of interest.  
Usually, a row of a dataset
- **Feature:** input variable.  
Usually a column of a dataset (1-dimensional array)
- **Label:** output variable (expected "answer" or "result").  
Usually, a column of a dataset
- **Dataset:** set of examples.  
Usually represented as a matrix (2-dimensional array)

More: <https://developers.google.com/machine-learning/glossary>

## Hyperparameters & Parameters

### Parameters

Internal values of the model learned during training

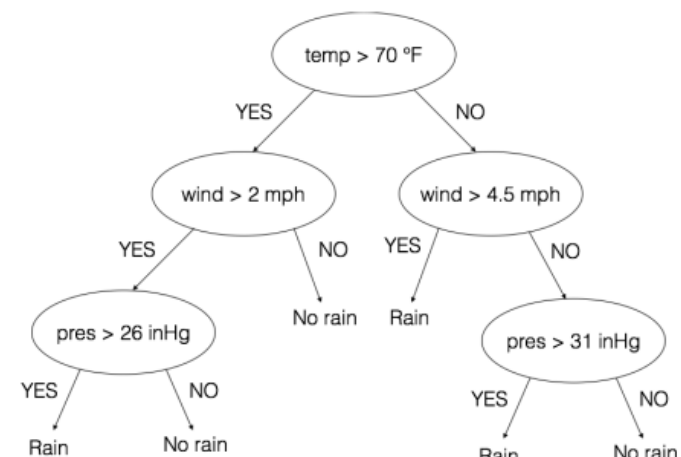

Learned values are called “Parameters Estimate”

E.g. feature and threshold of each node in a decision tree

### Hyperparameters

Values that influence the model and cannot be learned

E.g. depth of a decision tree

Example of a Decision Tree

# Machine Learning basics

Some considerations of  
Statistical Learning Theory

## How to learn from data?

$f(x_i)$  : the model's prediction for i-th example

**Loss:** a measure of how far a model's predictions are from its label

In binary classification:  $L(y_i, f(x_i)) = \mathbb{I}(y_i \neq f(x_i))$

**Empirical Risk:** Average of the loss across the dataset's examples

$$R_{emp}((X, y), f) = \frac{1}{N} \sum_{i=1}^N L(y_i, f(x_i))$$

**Empirical Risk Minimization:** finding a model that minimize the empirical risk

$$\min_f R_{emp}((X, y), f)$$

## Decomposition of the error

$$R(f_n) - R(f_{Bayes}) = \underbrace{(R(f_n) - R(f_{\mathcal{F}}))}_{\text{estimation error}} + \underbrace{(R(f_{\mathcal{F}}) - R(f_{Bayes}))}_{\text{approximation error}}$$

your trained model

“best” unknown model possible with the current set of features

best unknown model possible with the chosen algorithm (and the current set of features)

## Decomposition of the error

$$R(f_n) - R(f_{Bayes}) = \underbrace{\left( R(f_n) - R(f_{\mathcal{F}}) \right)}_{\text{estimation error}} + \underbrace{\left( R(f_{\mathcal{F}}) - R(f_{Bayes}) \right)}_{\text{approximation error}}$$

**VARIANCE**  $\longleftrightarrow$  **BIAS**

## Bias-Variance tradeoff

### Bias

Large approximation error, small estimation error  $\square$  **Underfit**

### Variance

Large estimation error, small approximation error  $\square$  **Overfit**

## Bias-Variance tradeoff

Oversimplification of the data

Learning the true signal

Fitting the noise of the data

## Bias-Variance tradeoff

# Interactive quiz

---

You trained a binary classifier (for example a spam filter) and you expect the same number of examples from both classes. You obtained the following accuracies:

- accuracy computed on the train set (the examples that were used to train the model): **99%**
- accuracy computed on the holdout set (the examples that were **not** used to train the model): **70%**

Do you think that the trained model is overfitting?

- True
- False

Same context, but now you obtained the following accuracies:

- accuracy computed on the train set (the examples that were used to train the model): **88%**
- accuracy computed on the holdout set (the examples that were **not** used to train the model): **87%**

Do you think that the trained model is overfitting?

- True
- False

Same context, but now you obtained the following accuracies:

- accuracy computed on the train set (the examples that were used to train the model): **61%**
- accuracy computed on the holdout set (the examples that were **not** used to train the model): **60%**

Do you think that the trained model is overfitting?

- True
- False

You want to classify images of cats and dogs. Your model takes as inputs pixels values of images, and outputs if the image corresponds to a cat (0) or a dog (1).

For this task you choose a decision tree. You set up a maximum depth of the tree of 8 (which means that for each image to predict your model will use at most 8 conditions to recognize a cat or a dog).

Is this model underfitting?

- True
- False

### Example of classification

Which one is overfitting, underfitting, or just a good fit?

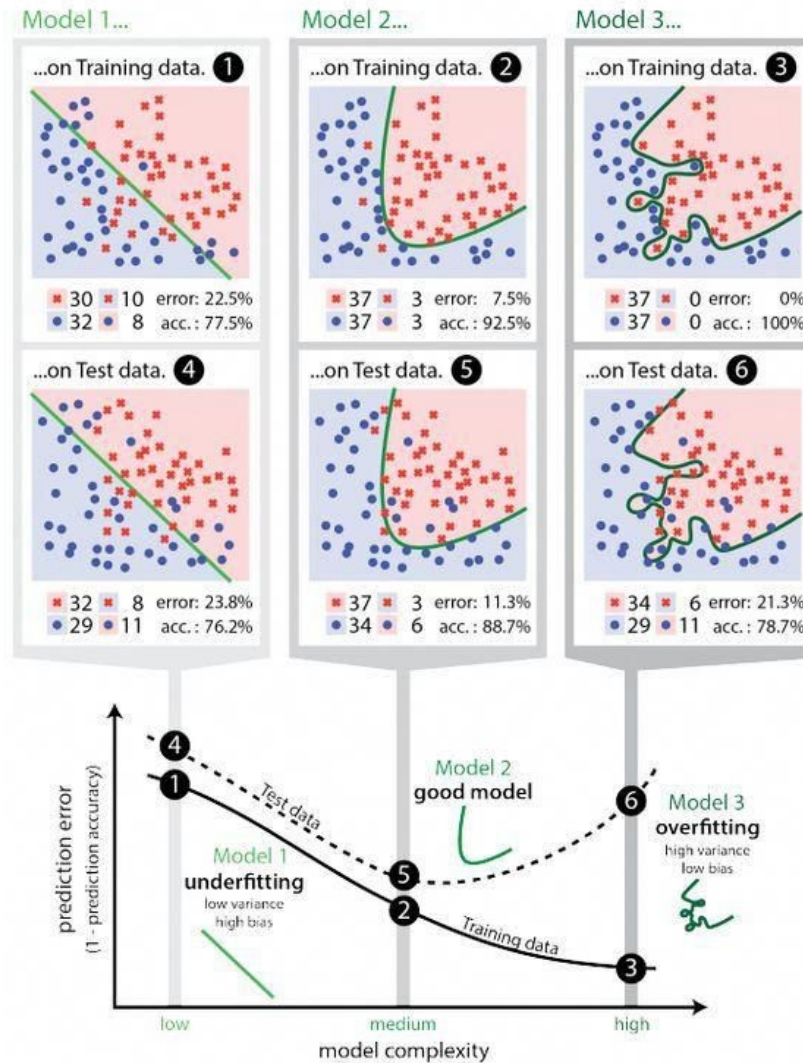

a)

b)

c)

# Overview of the life cycle of an ML project

---

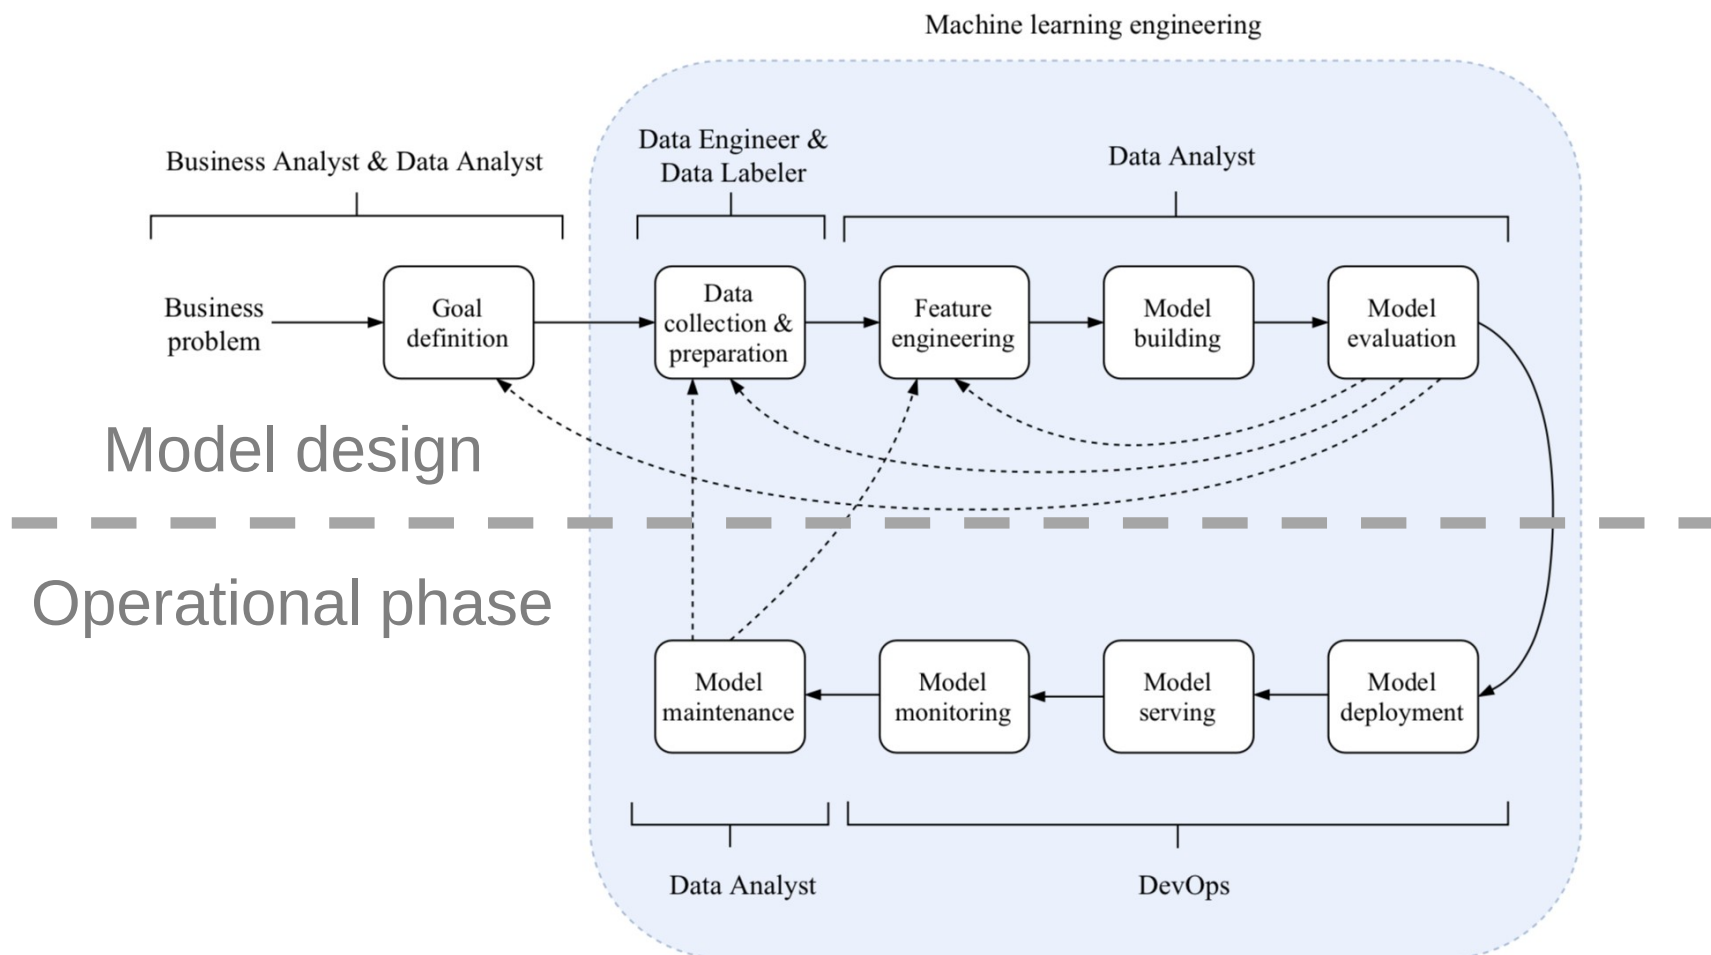

Figure 3: Machine learning project life cycle.

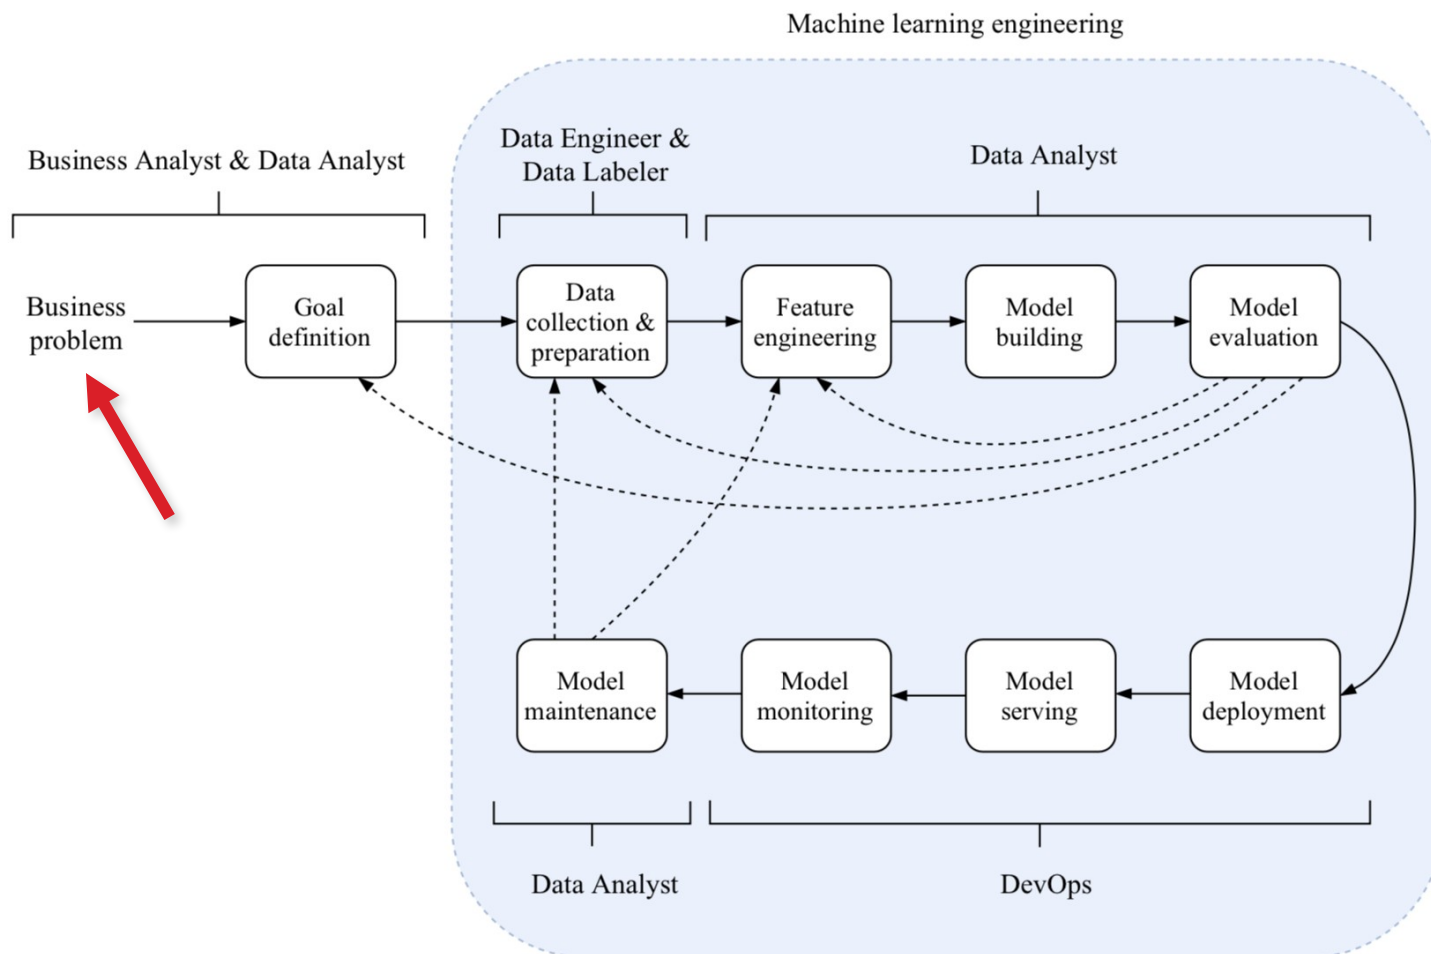

Figure 3: Machine learning project life cycle.

## When to use Machine Learning?

Consider using ML in those situations:

- the problem is too complex for coding
- the problem is constantly changing
- it is a perceptive problem (e.g. image, speech, and video recognition)
- it is an unstudied phenomenon
- the problem has a simple objective (e.g. yes/no decision, single number target)
- when it is cost-effective
  - 3 main costs: building the model, infrastructure to serve the model, model maintenance

When **not** to use Machine Learning?

## When **not** to use Machine Learning?

Probably better to not use ML when:

- getting right data is too complex or impossible
  - no relation between features and labels
  - the phenomenon has too many outcomes while you cannot get enough examples to represent those outcomes
- you know how to solve the problem using traditional software development at a lower cost
  - e.g. you can fill an exhaustive lookup table manually by providing the expected output for any input
- every decision made by the system has to be explainable
  - can be a GDPR requirement
  - idem for decision changes in similar situations over time
- the cost of an error made by the system is too high
- you want to get to the market as fast as possible

# Exercise

ML or not ML

Among the following situations choose the ones where you would use Machine Learning, and ones where it's much easier to use traditional software development.

- Compute the best play in a tic-tac-toe game:  
<https://en.wikipedia.org/wiki/Tic-tac-toe>
- Identify the human language of audio recordings (English, French, etc.)
- Develop the guidance system of a space rocket
- Identify where are forests using Satellite imagery
- Develop a word processing software, like Word
- Extract content from thousands of websites which all have different structures

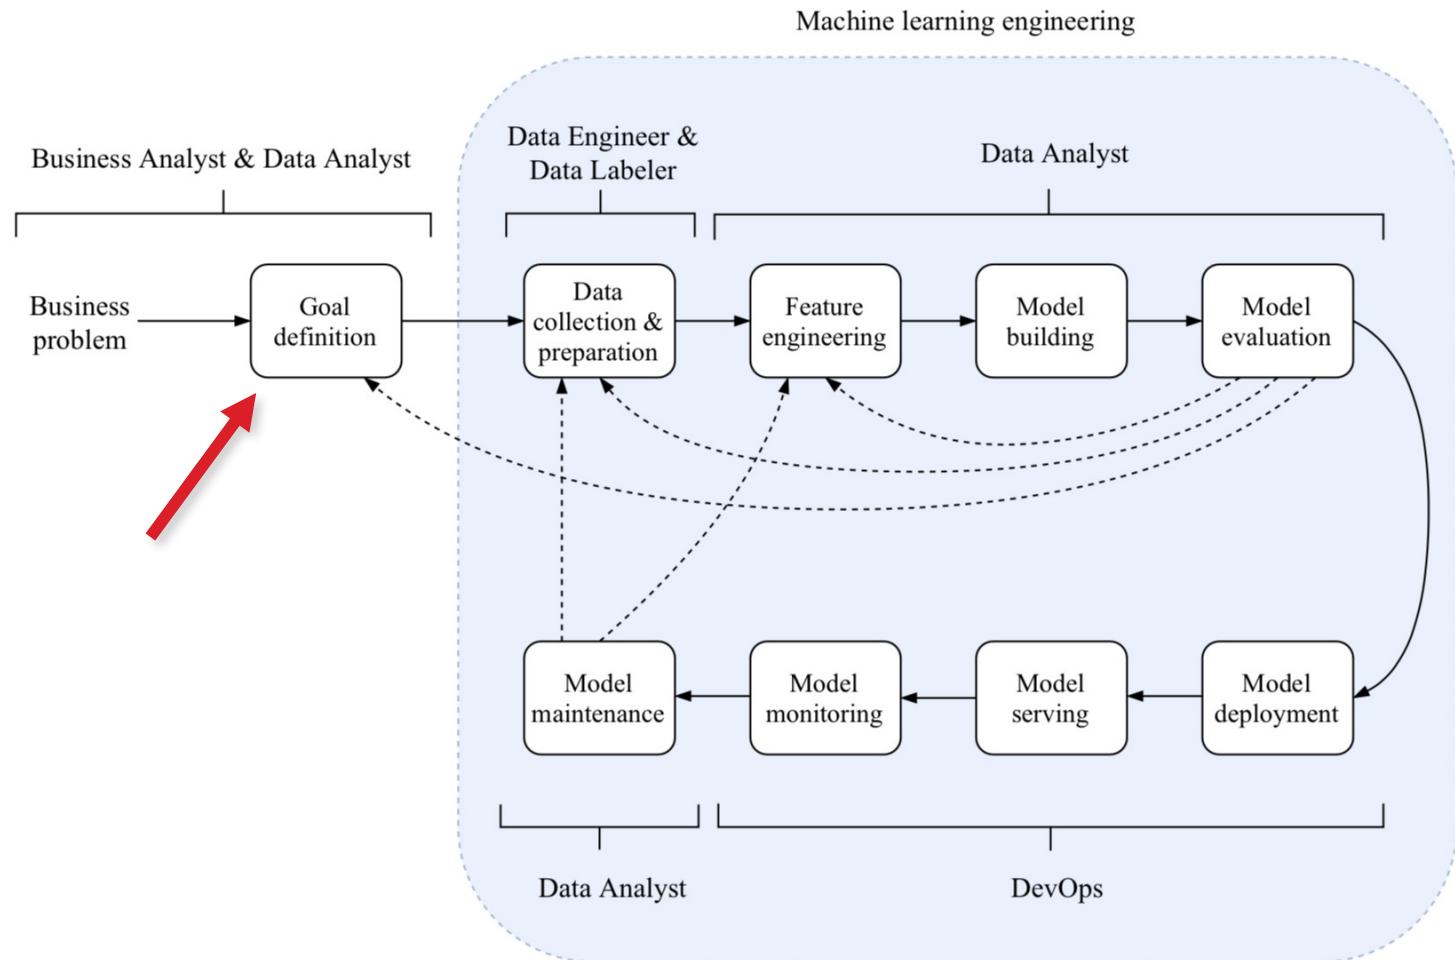

Figure 3: Machine learning project life cycle.

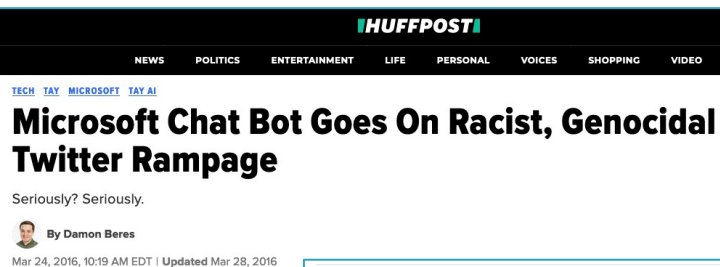

Write down the elements of your problem

- What is my objective?
- What is my task?
- What is an example?
- What is the expected output?
- What are acceptable behaviors? Unacceptable behaviors?
  - Think of performances, security, discriminations, privacy, ethical issues, etc.
- How to measure them?
- **Lastly**, do I have available data? If not, can I build a dataset?

- What are acceptable behaviors? Unacceptable behaviors?
  - Think of performances, security, discriminations, privacy, ethical issues, etc.

Don't skip this step. Afterthought will be too late.

MICROSOFT VIA TWITTER

**CNET** Your guide to a better future

Tech > Services & Software

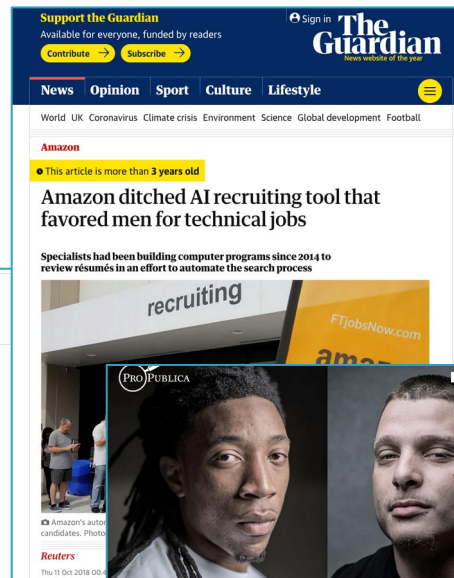

## Google apologizes for algorithm mistakenly calling black people 'gorillas'

The search giant is under fire after its Photo app offensively mislabeled user's photos. It points to another challenge Silicon Valley companies have to face when developing next-gen tech: sensitivity.

Richard Nieva  
July 1, 2016 5:32 p.m. PT

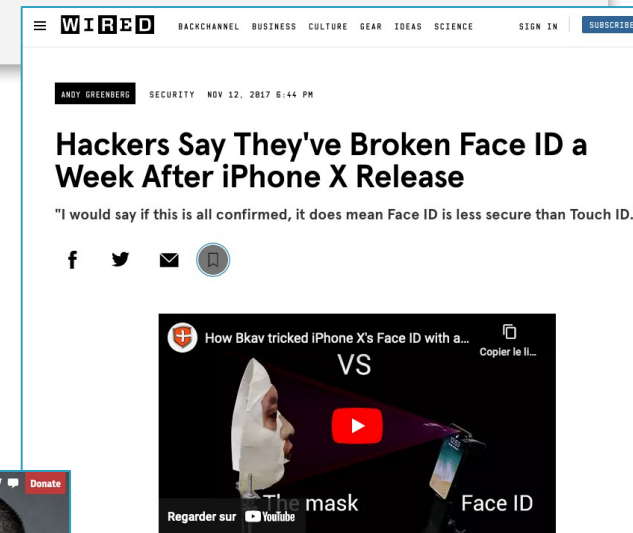

2 min read

## Machine Bias

There's software used across the country to predict future criminals. And it's biased against blacks.

by Julia Angwin, Jeff Larson, Surya Mattu and Lauren Kirchner, ProPublica  
May 23, 2016

## Example

Objective: be the best email provider

Task: automatically detect spam

Example: an email

Output: spam / ham

Acceptable behaviors:

- classify most of the spam, measured by probability of detection (sensitivity or recall) of at least 75%

Unacceptable behaviors:

- (performances) should only classify a very small amount of ham as spam, measured by specificity (true negative rate) of at least 95%
- (security) spammer should not find easy way to fool the spam filter
- (privacy) email content should not be leaked from the trained model

## Conduce a **Cost-Benefit Analysis**

- Learn more: [https://en.wikipedia.org/wiki/Cost%E2%80%93benefit\\_analysis](https://en.wikipedia.org/wiki/Cost%E2%80%93benefit_analysis)

### To estimate the **cost** consider:

- the difficulty of the problem
  - existing library
  - computation to train & serve the model
- the cost of data
  - can data be generated automatically?
  - cost of manual annotation  
labelling cats & dogs images  $\neq$  doctors labelling X-ray scans
  - how many examples are approximately needed
- the needed accuracy
  - how costly is each wrong prediction?
  - lowest accuracy level below which the model is impractical

Source image:  
A. Burkov, "Machine Learning  
Engineering".

## Data collection & preparation

In industry: 80% building dataset, 20% playing with it

Steps:

- Existing data:
  - access to existing data (negotiation, paperwork, anonymization, etc.), database work, merging datasets, etc.
- Creating a dataset
  - ⚠ can be very long
  - collecting data, statistical sampling, scraping, survey, labelling data, etc.
- Data cleaning
  - Domain validity, outliers, errors, duplicates, expired data, etc.

## Advices

Think of **reproducibility** from the beginning

- you might have to extract the same data again in the future: bugs, adding features, update data, etc.
- avoid manual labor on data in Excel: error-prone & difficult to traceback

Always check raw data and processed data

- Don't trust your implementation
- Keep backups of both datasets

Don't assume that your data is valid

- Check domain validity (e.g. postal code, age)
- Properly encode missing values (e.g. "-1", "99999"  $\square$  NaN)

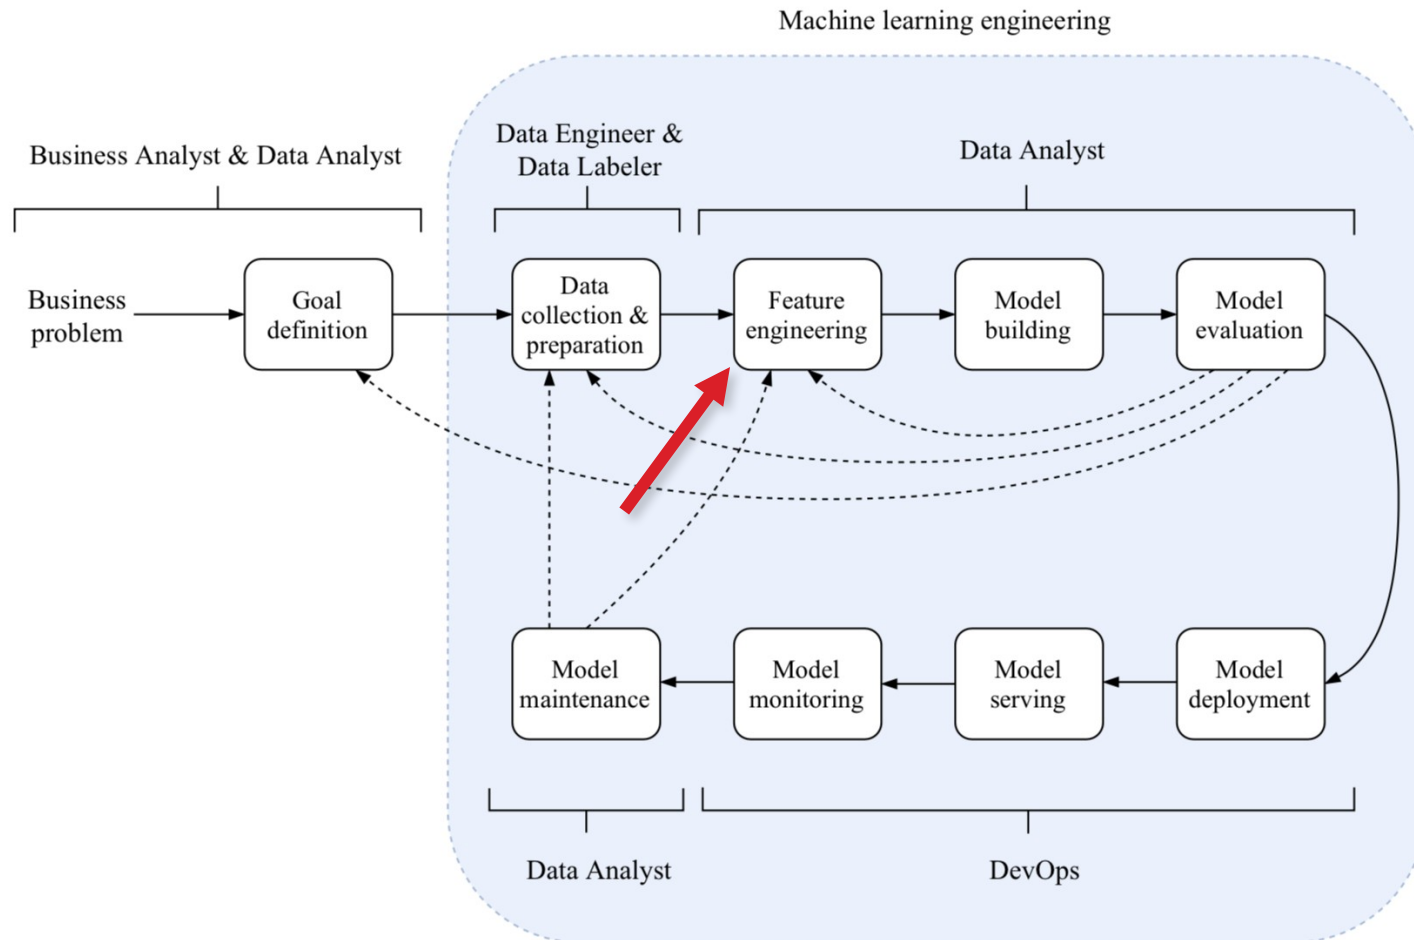

Figure 3: Machine learning project life cycle.

## Goal

Transform raw data into tidy data with numerical or categorical features

Example:

Plain text email ☐ Frequencies of “\$”, “!”, “#”, “viagra”, “buy”,  
“mail”, etc.

Average length of uninterrupted sequences of capital letters.

## Tidy data

Follow principles of **tidy data**:

- 1 row  $\square\square$  1 example
- 1 column  $\square\square$  1 feature
- single dataset

Sources of **messiness**:

- Column headers are values, not variable names
- Multiple variables are stored in one column
- Variables are stored in both rows and columns
- Multiple types of experimental unit stored in the same table
- One type of experimental unit stored in multiple tables

## Tidy data

	John Smith	Jane Doe	Mary Johnson
treatmenta	—	16	3
treatmentb	2	11	1

	×
--	---

person	treatment	result
John Smith	a	—
Jane Doe	a	16
Mary Johnson	a	3
John Smith	b	2
Jane Doe	b	11
Mary Johnson	b	1

See more examples of bad practices:

<https://www.jstatsoft.org/article/view/v059i10>

## Steps

1. Defining the features to represent well your examples
  - Usually involve domain experts
  - Document everything into a schema file (spreadsheet or Json with name, type, definition, missing values, source, etc.)
2. Implement their computation
  - reproducibility + checks
  - data manipulation: filter, transform, aggregate, sort

## Summarizing data

You can compute **mean & standard deviation** for each feature to aggregate

Example of Churn Analysis:

User

User ID	Gender	Age	...	Date Subscribed
1	M	18	...	2016-01-12
2	F	25	...	2017-08-23
3	F	28	...	2019-12-19
4	M	19	...	2019-12-18
5	F	21	...	2016-11-30

Order

Order ID	User ID	Amount	...	Order Date
1	2	23	...	2017-09-13
2	4	18	...	2018-11-23
3	2	7.5	...	2019-12-19
4	2	8.3	...	2016-11-30

Call

Call ID	User ID	Call Duration	...	Call Date
1	4	55	...	2016-01-12
2	2	235	...	2016-01-13
3	3	476	...	2016-12-17
4	4	334	...	2019-12-19
5	4	14	...	2016-11-30

User features

User ID	Gender	Age	Mean Order Amount	Std Dev Order Amount	Mean Call Duration	Std Dev Call Duration
2	F	25	12.9	7.1	235	0
4	M	19	18	0	134.3	142.7

Figure 25: Synthetic features based on sample mean and standard deviation.

## Steps

### 3. Encoding categorical features

- Models accept **only numerical** values
- Categorical features should be encoded as integers (**one-hot encoded**):
  - “male”, “female”, “female”  $\rightarrow$  0, 1, 1
  - “bachelor”, “master”, “bachelor”, “high school”, “master”  $\rightarrow$

0	1	0
0	0	1
0	1	0
1	0	0
0	0	1

### 4. Discretization of continuous variable (*optional*):

- Age: 8, 65, 42, 15  $\rightarrow$  “-18”, “50+”, “18-50”, “-18”  $\rightarrow$

1	0	0
0	0	1
0	1	0
1	0	0

## Steps

### 4. Missing data treatment

- Most models don't accept missing data
- Solutions: imputation, categorization, etc.

### 5. Data Normalization of continuous features

- I.e. mean removal and variance scaling
- Almost all models performs better with normalized data

### 6. Other features transformation $(X_1, X_2)$ to $(1, X_1, X_2, X_1^2, X_1X_2, X_2^2)$

- E.g, polynomial features:

## Practical advices

Informative features (high predictive power)

- Constant data are useless
- Totally unrelated features are not useful
- Duplicated features are not useful (e.g. weight in kg and in pounds)

Always check the presence of missing data

```
1 def transform_gender(value):  
2     if value == "male":  
3         return 0  
4     else:  
5         ! return 1
```

Use all data analysis tools to help you

- descriptive statistics (mean, standard deviation, min, max, quantiles, absolute and relative frequencies, etc.), data visualization, etc.

Use small sample to develop and debug

- Unit test for each data extractor

## When **not** to use Deep Learning?

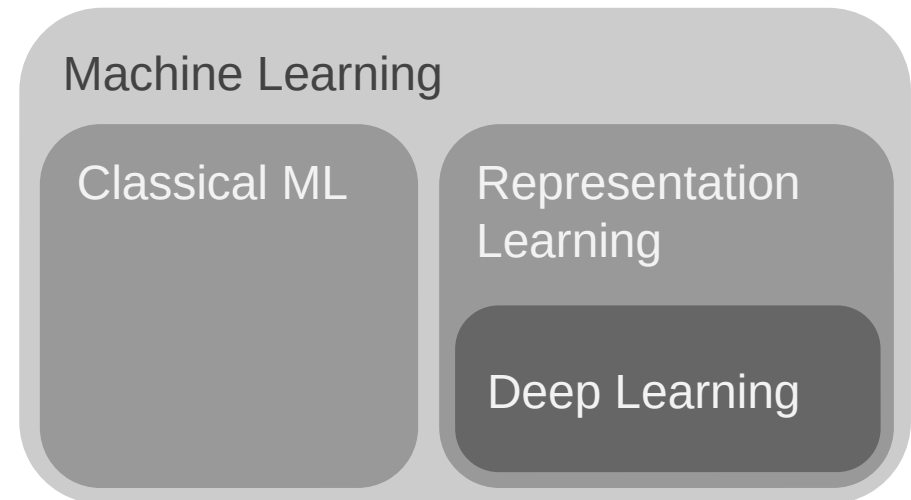

## Deep Learning

No feature engineering in Deep Learning

But has a cost

- number of examples (in millions)
- Complexity

Only consider DL if features engineering is complex, e.g., Computer vision, images of cats/dogs.

## No free lunch theorem

Theory said that there is no universally best model (Wolpert 1996)

Learning is impossible unless we make assumptions on the underlying distribution.

Figure 7. No free lunch theorem: Classifier 1 depicts a general purpose classifier. It performs moderately on all kinds of distributions. Classifier 2 depicts a more specialized classifier which has been tailored towards particular distributions. It behaves very good on those distributions, but worse on other distributions. According to the no free lunch theorem, the average performance of all classifiers over all distributions, that is the area under the curves, is identical for all classifiers.

- Some empirical guide can help you, e.g. this sklearn flowchart: [https://scikit-learn.org/stable/tutorial/machine\\_learning\\_map/index.html](https://scikit-learn.org/stable/tutorial/machine_learning_map/index.html)

## Practical advices

- Select models with the following criterion:
  - Explainability
  - Number of examples and features
  - Non-linearity of the data
  - Computational complexity
  - Prediction speed
- Choose model with best performances always evaluated with Cross Validation
- Don't forget to tune hyperparameters of model
  - Different strategies: grid search, random search, etc.

## Model Building Strategy

1. Define a performance metric  $P$ .
2. Shortlist learning algorithms.
3. Choose a hyperparameter tuning strategy  $T$ .
4. Pick a learning algorithm  $A$ .
5. Pick a combination  $H$  of hyperparameter values using the tuning strategy  $T$ .
6. Use the training set and build the model  $M$  using the algorithm  $A$  parametrized with hyperparameter values  $H$ .
7. Use the validation set and calculate the value of the metric  $P$  for the model  $M$ .
8. Decide:
  1. If there are still untested hyperparameter values, pick another combination  $H$  of hyperparameter values using the strategy  $T$  and go to step 6.
  2. Otherwise, pick a different learning algorithm  $A$  and go to step 5, or go to step 9 if there are no more learning algorithms to try.
9. Return the model for which the value of metric  $P$  is maximized.

## Overfitting ⚠

### Always use **Cross-Validation!**

- Split them into 3 distinct sets:
  1. Training set □ for model training
  2. Validation set □ for tuning hyperparameters & choosing models
  3. Test set □ for independent evaluation of your final model
- Good practice: split before at the beginning of data preparation step
- How to split?
  - Random subsets if examples are independent.
  - Use more complex splits if examples are dependent, e.g., time series

### Extreme case:

- Your model simply memorizes its training examples but returns random labels for new examples.
- Need to evaluate on “unseen” examples.

## Detecting Underfitting / Overfitting

## Detecting Underfitting / Overfitting

### Example of Regression

Oversimplification of the data

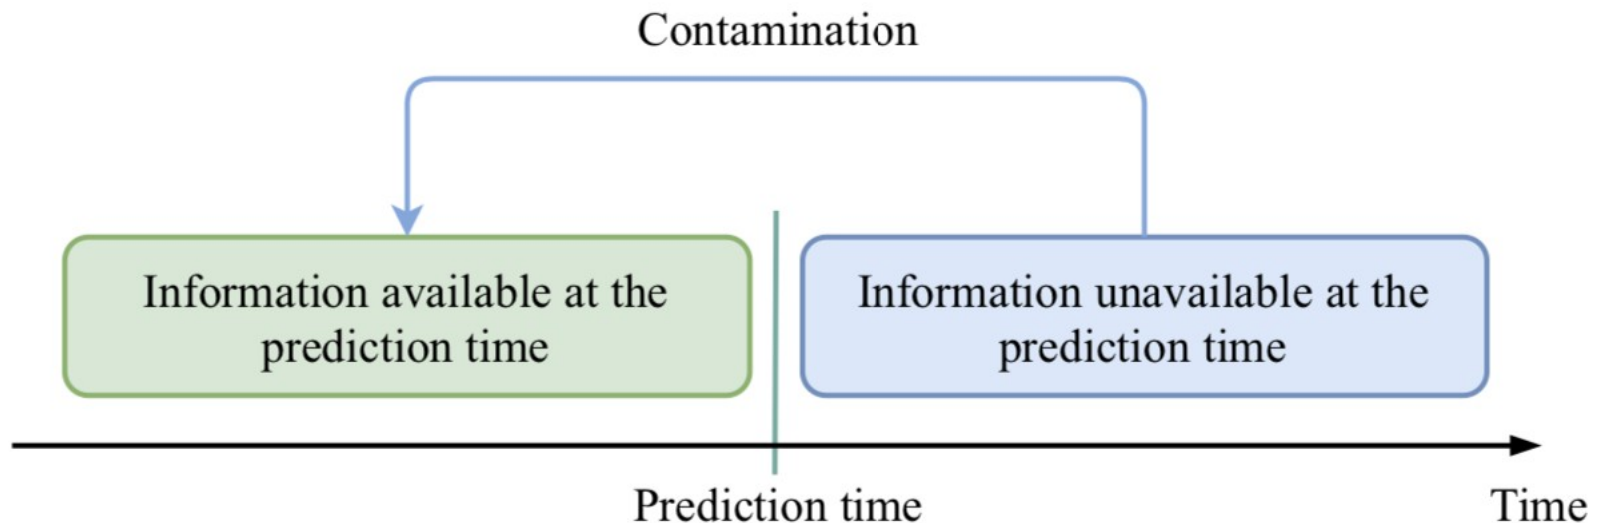

Learning the true signal

Fitting the noise of the data

## Data Leakage

Be careful to **data leakage** if your examples are not independent

## Choose an appropriate metric for your problem

- Report it computed on the test set
- Baseline:
  - performance of the simplest algorithm, usually random labelling
  - human performance

## Be careful to class imbalance problem

- Consider credit card fraud detection
- Probably have 1% of fraud among all transactions
- Accuracy isn't appropriate metric here: you can achieve 99% accuracy, just by classifying all transactions as genuine, which has 0 practical use
- In that case, metrics

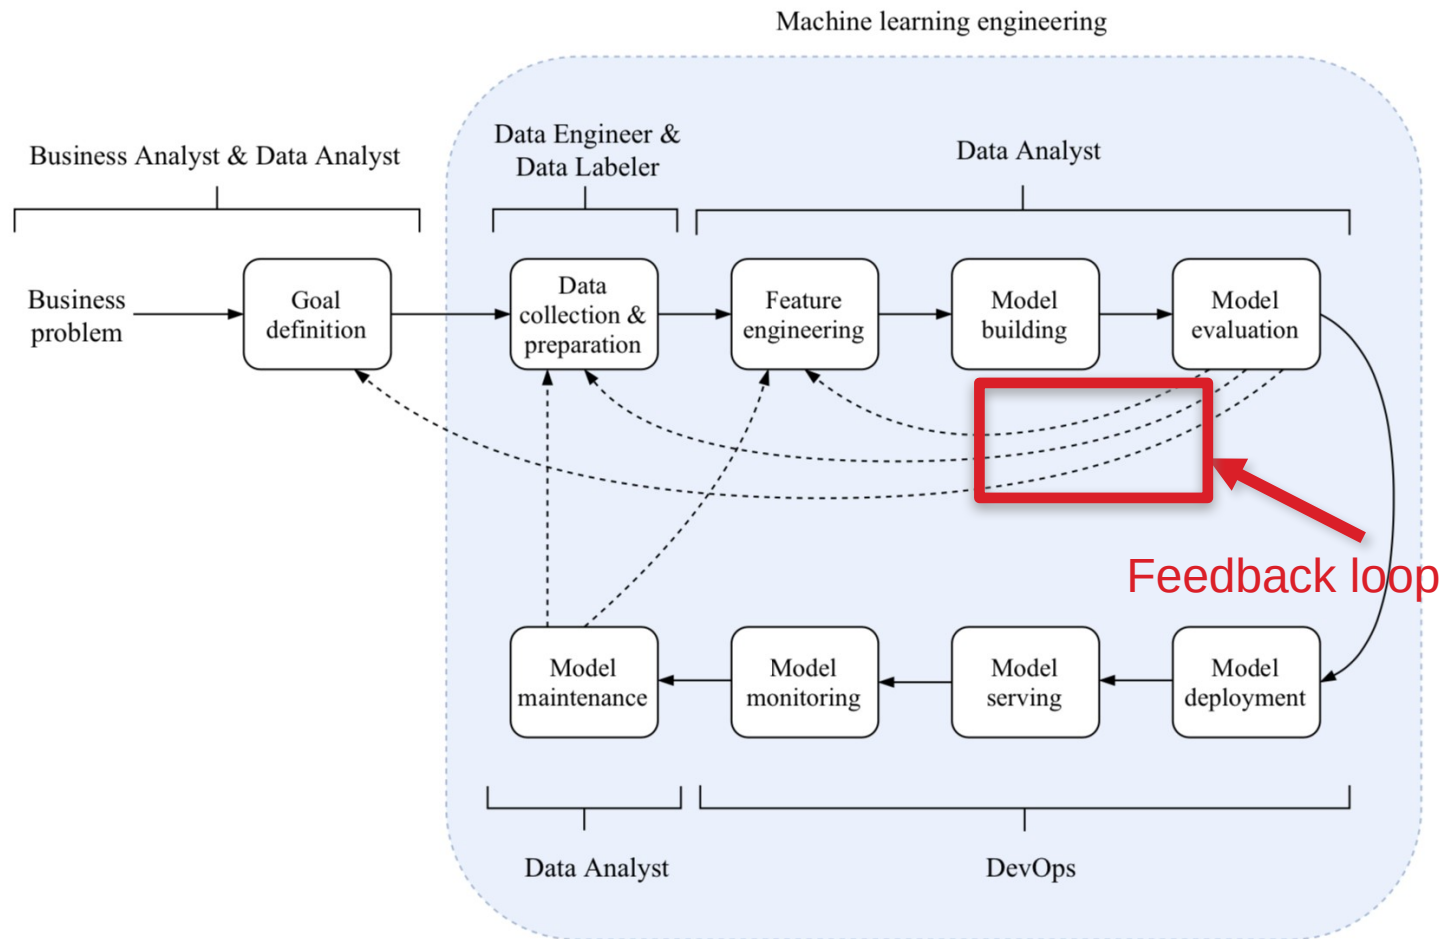

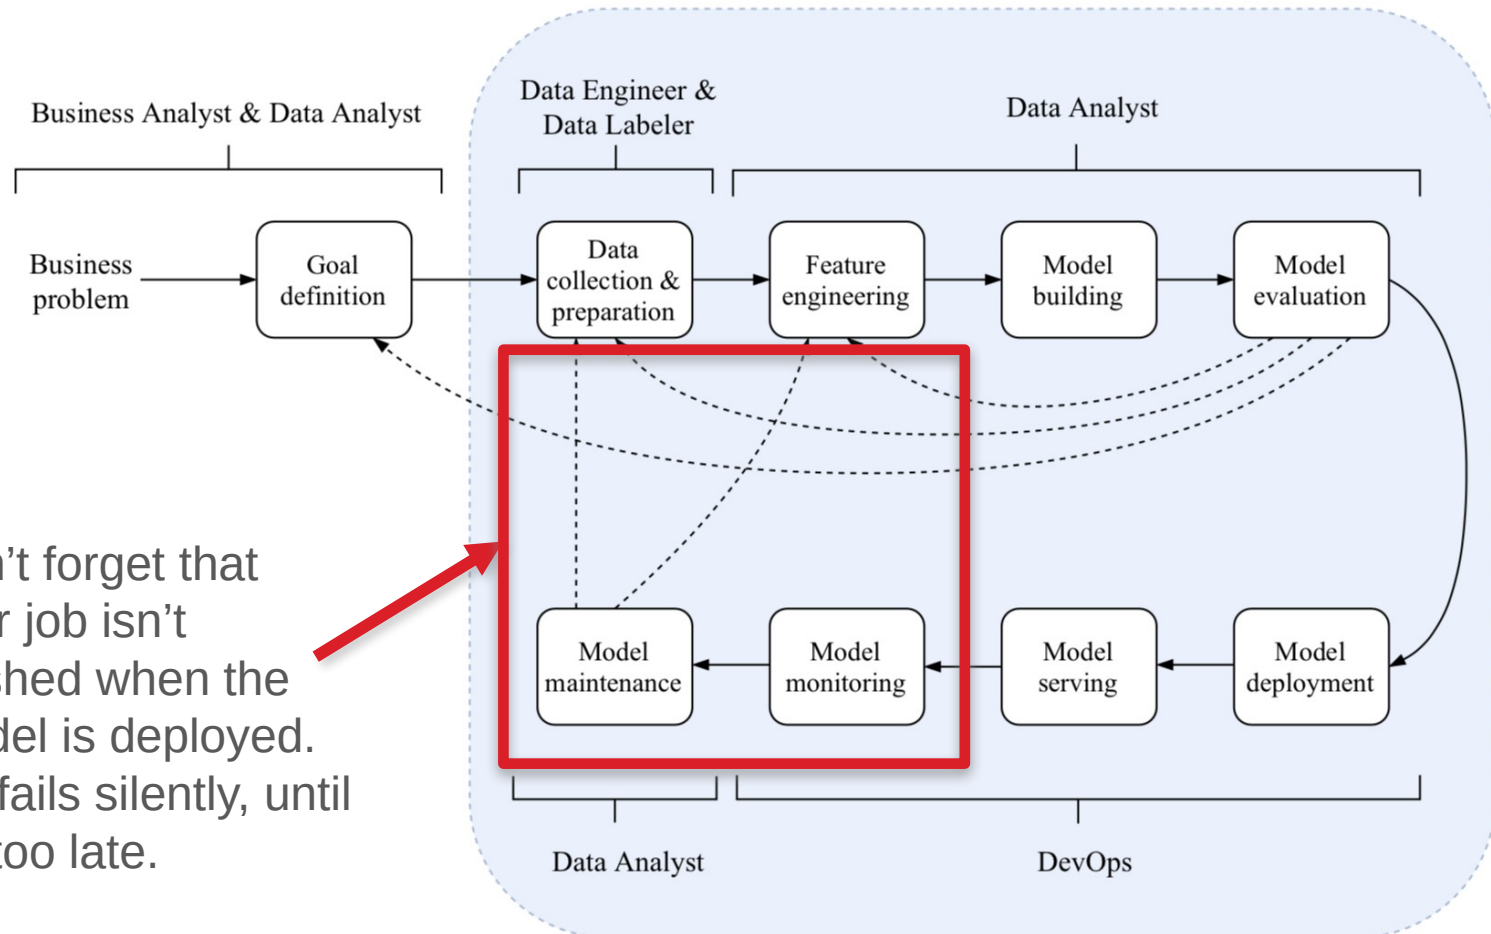

Figure 3: Machine learning project life cycle.

## Machine learning engineering

Don't forget that your job isn't finished when the model is deployed. ML fails silently, until it's too late.

Figure 3: Machine learning project life cycle.

# Quizz

ML or not ML

## Cost to increase accuracy

In general, the cost to train a model (ie. developers' time + computational needs) grows linearly with its accuracy

- True
- False

### Cross-validation

We want to predict the GDP of countries from its economics characteristics. We collect these variables for each year since 1900 and each countries. We shuffle all the data, keep-out 20% for the test set, and train a time-series model on the 80%.

What are the issues with this model?

## Is it tidy data?

country	year	m014	m1524	m2534	m3544	m4554	m5564	m65	mu	f014
AD	2000	0	0	1	0	0	0	0	—	—

MX17004	2010-02-11	tmax	29.7
MX17004	2010-02-11	tmin	13.4
MX17004	2010-02-23	tmax	29.9
MX17004	2010-02-23	tmin	10.7

(a) Molten data

id	date	tmax	tmin
MX17004	2010-01-30	27.8	14.5
MX17004	2010-02-02	27.3	14.4
MX17004	2010-02-03	24.1	14.4
MX17004	2010-02-11	29.7	13.4
MX17004	2010-02-23	29.9	10.7
MX17004	2010-03-05	32.1	14.2
MX17004	2010-03-10	34.5	16.8
MX17004	2010-03-16	31.1	17.6
MX17004	2010-04-27	36.3	16.7
MX17004	2010-05-27	33.2	18.2

(b) Tidy data

Table 12: (a) Molten weather dataset. This is almost tidy, but instead of values, the **element** column contains names of variables. Missing values are dropped to conserve space. (b) Tidy weather dataset. Each row represents the meteorological measurements for a single day. There are two measured variables, minimum (**tmin**) and maximum (**tmax**) temperature; all other variables are fixed.

# Exercise

Define your ML project

**First**, choose an application of Machine Learning. You can either choose:

- one covered in the course (except spam filtering)
- one that you are interested in (be creative!)
- to take inspiration from a list of applications:  
[https://en.wikipedia.org/wiki/Machine\\_learning#Applications](https://en.wikipedia.org/wiki/Machine_learning#Applications)

Don't worry, you can be creative and try (almost) anything! There is no "wrong" answers.

Then, write down the **elements of your problem**.

Element	Description
Objective	The general goal of your system
Task	The task of the sub-system considered
Example	The unit of data fed one per one to the model
Output	The prediction of one exemple
Acceptable behaviors	Regarding the acceptable and unacceptable behaviors, think in terms of <b>performances, fairness, security, privacy, ethical issues, etc.</b> Explain only the topics that make sense for your problem. One or two sentences for each topic that makes sense.
How to measure these acceptable behaviors	
Unacceptable behaviors	
How to measure these unacceptable behaviors
